

Introduction

[EN13788_RESULTS.xlsx](#)

Annex C of the standard EN ISO 13788¹ contains 6 examples of an interstitial condensation calculation and 1 example on drying of a wetted layer.

The following validation examples will be simulated with the CONDENSATION feature in the program TRISCO.

- C2 Example 1: Building component with condensation in one interface plane
- C3 Example 2: Building component with condensation in two interfaces*
- C4 Example 3: Building component containing a well ventilated cavity
- C5 Example 4: Building component in a warm humid climate
- C6 Example 5: Division of a layer with high thermal resistance
- D Example of the calculation of the drying of a wetted layer

* This validation example is excluded here as the data mentioned in EN ISO 13788 contains errors. The discussion of this example can be found in Annex A of this document.

Boundary conditions

Several of the validation examples make use of the boundary condition given in Annex C.1. Figure 1 shows the monthly mean external (side 1) and internal (side 2) temperature and relative humidity.

Month	External		Internal Normal occupancy		Internal High occupancy	
	θ_e °C	φ_e %	θ_e °C	φ_e %	θ_e °C	φ_e %
January	-1	85	20.0	39	20.0	49
February	0	84	20.0	40	20.0	50
March	4	78	20.0	44	20.0	54
April	9	72	20.0	49	20.0	59

C.2-Example 1: Condensation at 1 interface

[C2_NORMAL.trc](#)
[C2_HIGH.trc](#)

In this example, a flat roof with an impermeable weather proofing layer over the insulation is analysed. Figure 2 shows the roof built-up. The roof is analysed for both the normal and high occupy levels.

Figure 2. Layers and interfaces in roof

The geometry modelled in TRISCO with blocks. Also for the small layer (e.g. vapour check) blocks are used.

Figure 5. TRISCO results for example C.2 compared with the standard

Figure 5 shows the condensation rate and the condensation accumulation rate obtained by TRISCO and listed in the standard, both for a situation with a normal and a high occupancy. The rates are practically identical.

C.4-Example 3: Building component containing a well-ventilated cavity

In this validation example no condensation or drying is found. Consequently, this validation case is not relevant for validation purposes and is thus excluded here.

C.5-Example 4: Building component in a warm humid climate

[C5_HUMID.trc](#)

In this example a timber framed wall is analysed in warm humid climate conditions. The wall is presented in the figure below.

Figure 6. Layers and interfaces in timber framed wall

C.6-Example 4: Division of a layer with high thermal resistance

[C6_HUMID.trc](#)

In this example a wall built from lightweight blockwork with internal insulation is analysed. Both the blockwork and insulation have a thermal resistance greater than 0.25 m²K/W, so the blockwork is divided in 10 layers and the insulation in 2 layers (see section 6.4.1 in EN ISO 13788)

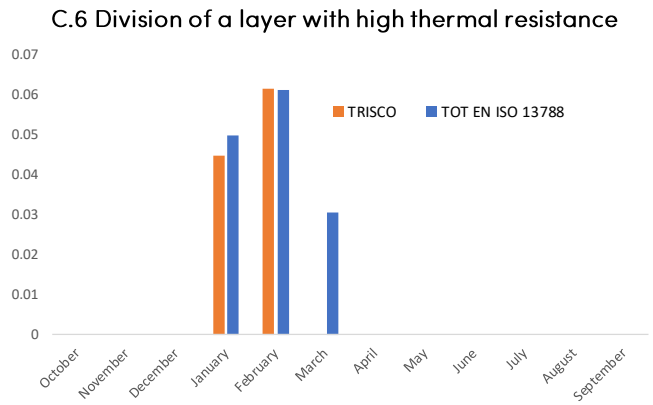

Figure 14. TRISCO results compared with the standard

D – Example of the calculation of the drying of a wetted layer

[D_HIGH.trc](#)

This example assumes that the insulation, layer 3 in the flat roof shown in the figure below, has been wetted by precipitation during construction before the installation of the weatherproof membrane. To do this, the insulation layer is divided into two and it is assumed that there is excess moisture content of 1 kg/m² at interface I2.

The climate conditions correspond to C.1 with high occupancy.

Figure 15. Layers and interfaces in roof

The material properties used for each layer in TRISCO are shown in table below:

Col.	Type	Subtype	Physical flow dir.	Name	λ [W/mK]	μ [-]	θ [°C]	RH [%]	h [W/m ² K]	Standard

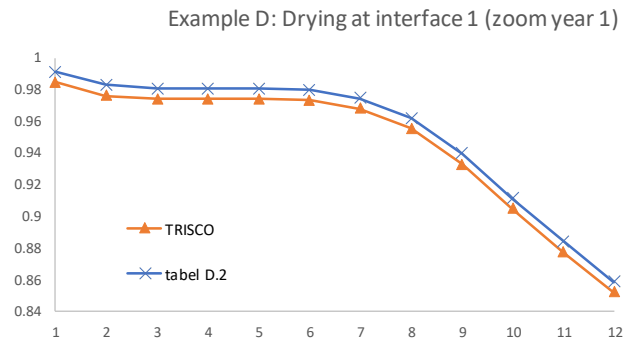

Figure 18. TRISCO results compared with the standard (first year)

The graph below shows that the roof is dried out after a period of 83 months which is in line with the results from EN ISO 13788.

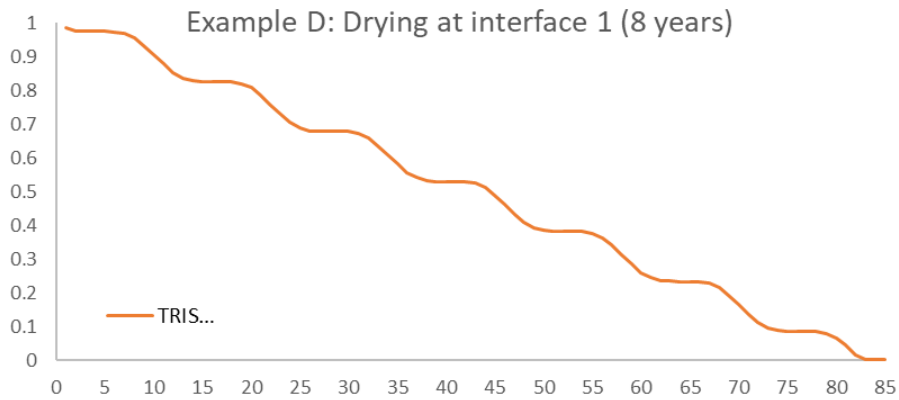

Figure 19. TRISCO results compared with the standard (8 years)

ANNEX A

C.3 – Example 2: Building component with condensation in two interfaces.

[C3_HIGH.trc](#)

In this example, a flat roof with an extra 100mm of insulation added below the vapour control layer is studied (Figure 20). The roof was analysed in **high** occupancy levels.

The geometry is modelled in TRISCO with blocks. Also for the small layer (e.g. vapour check) blocks are used as shown in Figure 21.

Figure 20. Layers and interfaces in roof

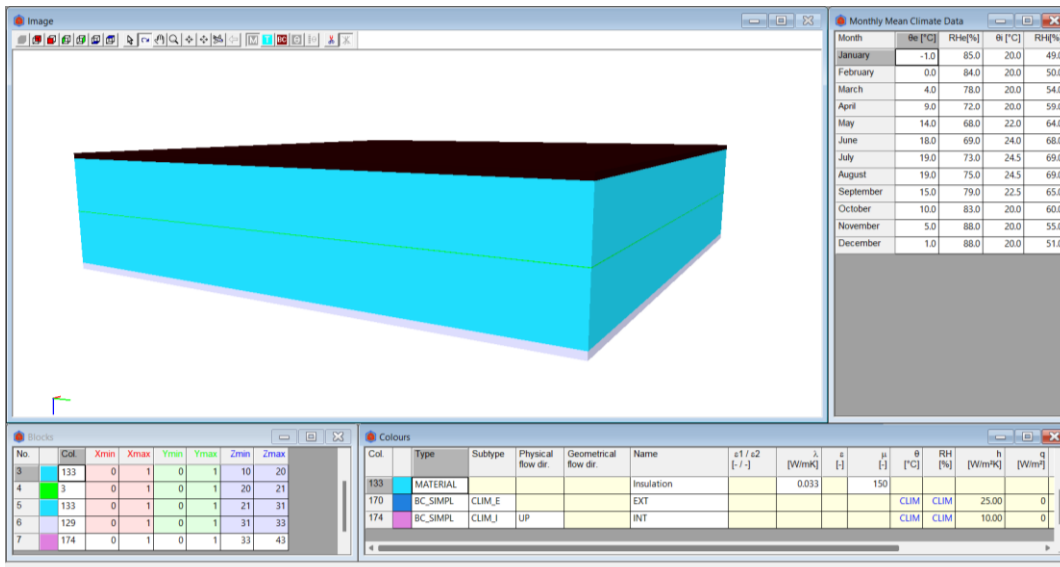

Figure 21. Material properties in TRISCO

To be in line with EN ISO 13788 select a vapour permeability of air equal to $2 \cdot 10^{-10}$ kg/(m.s.Pa) and condensation only on surface.

Figure 22 and Figure 23 shows the condensation rate and the condensation accumulation rate obtained by TRISCO and EN ISO 13788.

From December to April, at interface 1, the condensation rates from TRISCO and EN ISO 13788 were identical. However, from May to October, TRISCO indicated evaporation, while EN ISO 13788 reported persistent condensation at interface 1 throughout the year.

Figure 22. TRISCO and EN ISO 13788 results

ENISO13788 C3 high occupancy

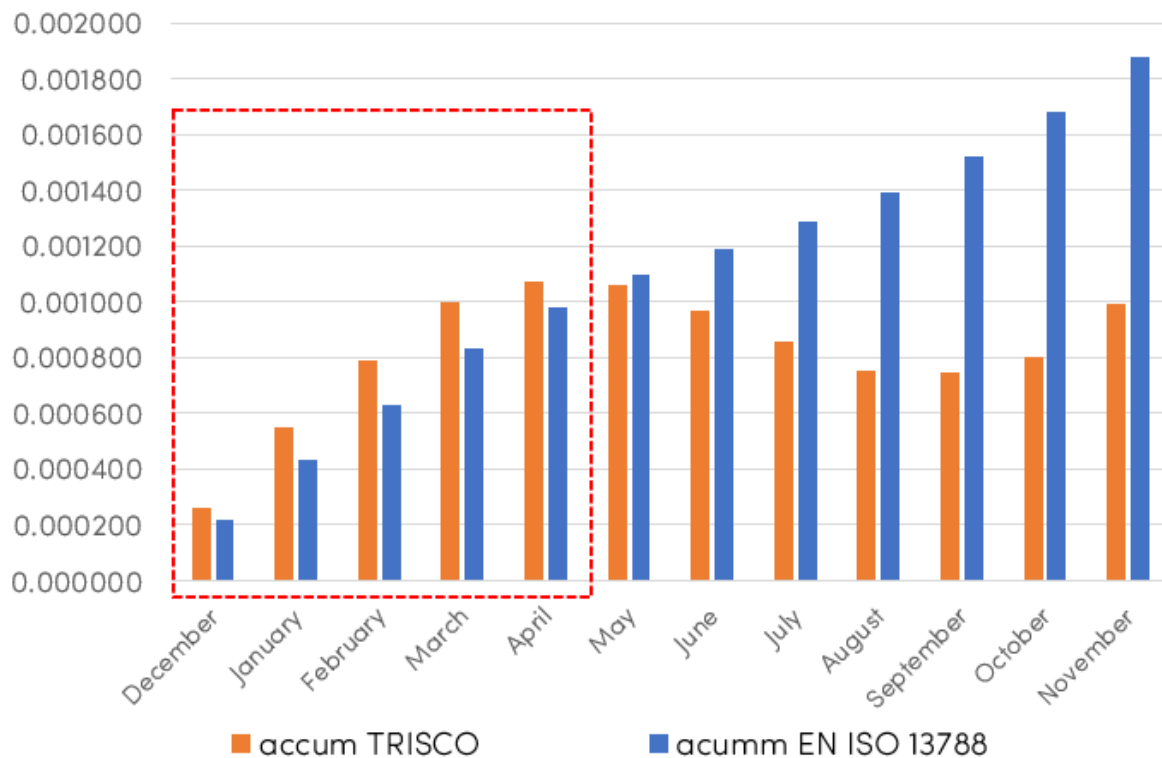

Figure 23. TRISCO and EN ISO 13788 accumulation rate

At interface 3, EN ISO 13788 showed condensation occurring from December to March, whereas TRISCO showed no condensation at this interface. To verify the findings, the Glaser method was applied, and the results below align with TRISCO, showing interstitial condensation only at interface 1 and no condensation at interface 3 for the month December.

	Interface	Z tot (s.m2.Pa)/kg	Pv	Pv sat
